Paper Ref #2319

The Use of New Condition Assessment Technologies for Selecting Trenchless Rehabilitation of Wastewater Networks in Ras Al Khaimah, UAE

Abdul Qadir Malik¹

¹ Head of Capital Projects, Ras Al Khaimah Wastewater Agency, UAE

ABSTRACT

The Ras Al Khaimah Wastewater Authority (RAKWA) manages wastewater collection and treatment of sewerage in the emirate of Ras Al Khaimah (RAK) – the fourth largest of seven emirates of the United Arab Emirates (UAE). Having the most fertile soil in the country, due to a larger share of rainfall and underground water streams from the Hajar mountains, combined with a growing number of resorts taking advantage of Gulf beaches, RAKWA is undertaking a series of major wastewater rehabilitation and expansion projects supporting a population of nearly 420,000 people.

Representing over 14.5km of recently installed plastic and fiberglass reinforced pipe, RAKWA targeted its City West Trunk Main, Mairid Network and Force Main Network – Area 1 Project, a currently 'inactive' network, for addition to the city's growing underground wastewater network, requiring innovative condition assessment, prior to its addition to the collection system.

RAKWA engineers had noticed numerous sections of the 'new' network were experiencing high levels of infiltration, initially approved by high resolution CCTV cameras. Located on the Arabian Sea, tidal infiltration is a constant threat resulting in infiltration and exfiltration. As a result, prior to connecting lateral services to the network, RAKWA decided to incorporate Focused Electrode Leak Location (FELL) to identify and quantify specific leak locations for Fiberglass UV-Cured Trenchless Rehabilitation.

FELL had been recommended in a recent Masterclass by UK-based WRc and is supported by ASTM F2550, leading to RAKWA's decision to use both IBAK Panorama CCTV and FELL technologies. While Gulf authorities have commonly relied on CCTV of their pipes, defects at joints and manhole connections many times have gone unnoticed, adversely affecting network performance.

This paper shares results from the first major benchmark of CCTV & FELL technologies in the Gulf and discuss selection parameters to conduct 3.5km of UV-cured CIPP and 310 patches or sectional liners.

INTRODUCTION

The Ras Al Khaimah Wastewater Authority (RAKWA) faced a challenge: when and how to connect residential and commercial businesses in the Al Mairid area to the sewerage network covering over 550 plots. Customers looked forward to eliminating septic tanks that frequently resulted in foul odours from regular tank emptying and cleaning, and occasional overflow during heavy rains.

Yet, despite the installation of new plastic and fiberglass reinforced sewer pipes, significant levels of tidal infiltration were occurring – without a single home or business connected to the system.

With 'new' sewers already fully infiltrated, without a single customer connection, and the need to prioritise repairs and rehabilitation without risking repeating past errors, RAKWA leadership needed to either utilise legacy camera-based visual optics or use untested high technology-based low voltage conductivity to find leaks. So, RAKWA decided to do both.

ABOUT RAS AL KHAIMAH, UAE

Representing the fourth largest Emirate covering an area of 2,486 square km (960 sq mi), or nearly 3 percent of the total UAE land area, Ras Al Khaimah, which means 'Top of the Tent' in Arabic, is located near the northernmost point of the United Arab Emirates, and shares a mountainous border with the Sultanate of Oman and three other Emirates which are Fujairah, Sharjah, and Umm Al Quwain, as shown in Figure 1.

Located on the waters of the Arabian Gulf with 64 km (40 mi) of sandy coastline, supporting a population of 420,000, average temperatures range from 12 to 25 °C (54 to 77 °F) in January and 29 to 43 °C (84 to 109 °F) in July. However, temperatures often reach 45 °C during summer months, reaching its highest recorded temperature of 48.8 °C (119.8 °F). Rains occur rarely, and only in winter, with snow reported in December 2004, January 2009 and February 2017 at the peak of Jebel Jais, the highest mountain in the UAE.

Figure 1. Ras Al Khaimah, UAE

CITY WEST TRUNK MAIN, MAIRID NETWORK AND FORCE MAIN NETWORK PROJECT

Representing over 14.5km of recently installed plastic and fiberglass reinforced pipe, RAKWA targeted its City West Trunk Main, Mairid Network and Force Main Network – Area 1 Project, a currently 'inactive' network, for addition to the city's growing underground wastewater network, requiring innovative condition assessment, prior to its addition to the collection system.

RAKWA engineers had noticed numerous sections of the 'new' network were experiencing high levels of infiltration, illustrated in Figures 2 & 3, initially approved by high resolution CCTV cameras. Located in close proximity to the Arabian Sea, tidal infiltration is a constant threat for infiltration and exfiltration.

As a result, prior to connecting lateral services to the network, RAKWA decided to incorporate Focused Electrode Leak Location (FELL) to identify and quantify specific leak locations for Fiberglass UV-Cured Trenchless Rehabilitation.

A new technology that had never been used in the Gulf, referred to as Focused Electrode Leak Location (FELL) or Low Voltage Conductivity, had been recommended in a recent Masterclass presented by UK-based Water Research Centre (WRc) plc. Supported by the American Society of Testing and Materials (ASTM) F2550, RAKWA leadership decided to use both FELL technology and traditional camera-based visual optics, utilising iBAK's Panorama camera for the project. Representing the largest CCTV | FELL benchmark test of its kind in the world, RAKWA looked forward to automatically comparing pre- and post-rehabilitation effectiveness, not available by using CCTV cameras.

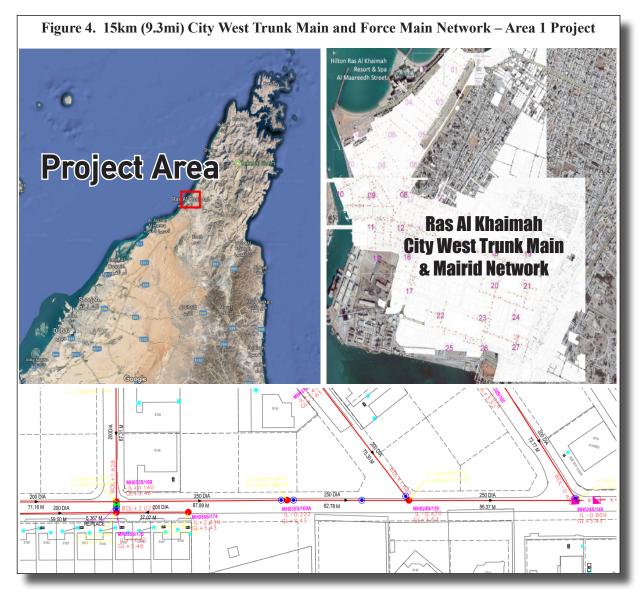

Figure 3. Surcharged 'Inactive' Sewer Main

PROJECT SCOPE

As illustrated in Figure 4, RAKWA wished to identify specific locations of the 'inactive' network to undertake targeted trenchless rehabilitation and patch repairs, based on relevant condition assessment data from legacy CCTV inspection and next generation FELL machine-intelligent tethered instrumentation.

Issuing a formal tender for a selected contractor to undertake a 15km (9.3mi) investigation and complete repairs and rehabilitation in consultation with RAKWA's consulting engineer, Riyadh-based International Aramoon Co., Ltd. (IAC) was selected to complete visual inspection using German-manufacturer iBAK Panorama 360-degree camera technology and FELL machine-based instrumentation using American-manufacturer Electro Scan Inc.

Due to the requirement for CCTV and FELL inspection to utilize a common measurement system for positioning defects, FELL technology was retrofit into a Rausch manufactured CCTV van as show in Figure 5.

Figure 5. FELL Technology in Ras Al Khaimah

CCTV | FELL BENCHMARK RESULTS

Visual inspection has been a mainstay in RAKWA's condition assessment strategy, to assess the condition of its sewer mains. In the past, infiltration sources were difficult to identify because CCTV inspections needed to be completed with low or no flow conditions.

Given high groundwater areas and the invasive dynamics of tidal infiltration that can often impact sewer mains up to 2km away from ocean or waterways, it was often necessary to bypass flows of sewers to create lower flow conditions to identify defects. Video inspections can also fail to recognize defects in the sewer that contribute infiltration unless the CCTV occurs when infiltration is active.

In contrast to manual-based CCTV inspection, FELL inspection incorporates a machine-intelligent capability to automatically identify and quantify defects without third-party data interpretation or reliance on expert technicians to identify, classify, or code defects.

A detail review was made for each sewer main and summarized in Tables 1, 2 and 3. CCTV and FELL readings were compared for each sewer main, including side-by-side analysis showing locations of each defect. The uniformity of defects shown by FELL testing indicated a 100% correlation to pipe joints, with only minor discrepancies in comparing CCTV defects not found by FELL which occurred when insufficient water levels were not achieved in the field attributed to high rates of pipe exfiltration.

Basic components of Plastic Pipe and common pipe defects are shown in Figures 6, 7, & 8, with examples CCTV and FELL results for the same sewer main provided in Figures 9 & 10.

CCTV | FELL DEFECT IDENTIFICATION IN PLASTIC PIPES

The Gulf states utilise an abundance of plastic pipe for sanitary sewer and water installations, including High Density Polyethylene (HDPE) and Polyvinyl Chloride (PVC). While the utmost in care is used in the manufacturing process, transportation, installation, and prolonged heat, prior to pipe laying, can play havoc with newly installed pipes, as shown below. Poor installation is the Number 1 cause for most pipe defects, especially in the case of poorly placed gaskets and improperly sealed joints.

Easy to Detect 'Visual' Problems. A detailed review of Post-Installation / Pre-Commission of PVC sewer pipes can show obvious problems that should not be identified months or years after installation. Improperly sealed joints, poorly placed gaskets, and collapsed pipes should never be accepted if properly evaluated prior to acceptance, as shown in Figure 7 (*Below*).

Figure 7. Examples of Easy to Detect and Catalog Pipe Defects

'Invisible Sources' of Pipe Leakage Missed By Closed-Circuit Television (CCTV) Inspection. A key finding of the RAKWA condition assessment project was the confirmation of 'invisible' defects, i.e. defects at joints not readily observed by CCTV operators, QA/QC personnel or consulting engineers, as shown in Figure 8 (Below).

Figure 8. Examples of Difficult to Detect and Catalog Pipe Defects

FELL REPEATABILITY TESTING

A key advantage of low voltage testing, and reason for adopting FELL watertightness testing, is its ability to replicate survey results, regardless of equipment, software versioning, crew operation, or soil resistivity. As shown in Figure 11, multiple tests were conducted using both forward and backward field testing of the FELL tethered-mounted machine-intelligent probe.

Similar tests had been previously documented by US Environmental Protection Agency (EPA) studies, a Water Environment & Reuse study, and customer benchmarks, including Same-Day Testing conducted by WRc, 60-Day Test Comparisons by the USEPA, and separate agency testing of over 240-days between FELL tests, including different crews, probes, and CCTV cables & reels.

Key benefits of FELL technology, include:

- Unbiased test results, without third-party data interpretation.
- Locational accuracy of 1cm (0.4in)
- Severity of each defect in l/s or gpm.
- Soil type & resistivity agnostic.
- Limited susceptibility to false-positive readings (i.e. unambiguous detection of faults on all non-conductive pipe materials).
- Hydrogeological (i.e. groundwater) independence.
- Works with CCTV cabling, reel, or internal architecture.
- Avg. production rate of 10-15m/min (45-60ft/min).
- Capable of working in diameters from 76mm 1200mm (3in 48in).
- Ability to measure Pre- and Post-Rehabilitation Effectiveness immediately after pipe repair or curing.
- COMSOL Multiphysics certification.

Due to poor original construction and acceptance based on visual inspection using CCTV cameras, new standards for water tightness were implemented on all new and rehabilitated pipes.

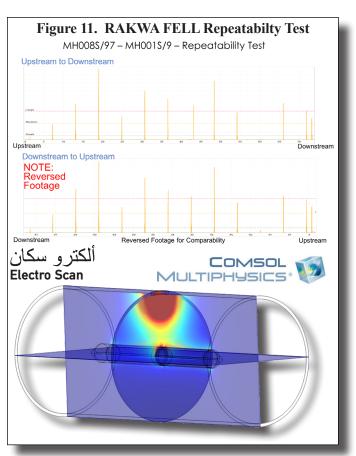

REHABILITATION SELECTION CRITERIA

Based on results from the condition assessment field surveys, including detailed comparisons of results from CCTV and FELL, RAKWA management directed its consulting engineers to use the following guidelines shown in Figure 12, to plan and execute rehabilitation.

8	
Pipeline Defect or Characteristic	Rehabilitation Selection
FELL Severe Defects (Measured by Liters per Second)	CIPP
Extended 5% Deflection limits of 25% of the length of the line	CIPP
Deflection of more than 10%	CIPP
Open Joints of More Than 20mm	Patch
Leaking Joints	Patch
Intruding Gaskets or Other Material	Cutting & Patch
More Than 4-5 Patches in a Line	CIPP
Low Groundwater	CIPP

Figure 12. RAKWA Mandated Rehabiitation Selection Criteria

Prior to the investigation, an initial rehabilitation budget was to be limited to 375 patches (i.e. sectional point repairs) and 4.5 km of CIPP lining. As a result of FELL testing, rehabilitation was reduced 23% from 4.2km to 3.25km, representing a savings of 1.2M AED. In addition, Patch Repairs were reduced from 373 to 320 patches, representing a savings of 320,000 AED, for a total project savings of 1,520,000 AED. Six months after project completion, ZERO (0) metered flow was measured and confirmed at the associated pump station, indicating 100% reduction in infiltration.

CONCLUSIONS

The days of unlimited capital spending on infrastructure management projects are over, as agencies must use greater care in the prioritisation and selection of capital schemes and measured benefits. Capital efficiency is now a key goal for every new project. In addition to better standards for accepting contractor's new installations, increased standards for watertightness testing must also extend to repairs and rehabilitation as hydrostatic pressure testing of sewer mains and visual optics are insufficient to guarantee workmanship.

Finally, agencies should not fear new technologies, but test results.

ABOUT THE AUTHOR

Abdul Oadir Malik

Head of Capital Projects, Ras Al Khaimah Wastewater Agency Email: abdul.malik@pwsd.rak.ae

Mr. Abdul leads design, development and construction projects at RAKWA, in addition to coordinating with various federal, state, and regional jurisdictions, as well as with special-interest groups, stakeholders and the public. Since joining RAKWA in 2015, he has planned and managed all aspects of project design, development and implementation of capital projects, including technical research & analysis, funding & cost analysis, scheduling, public involvement, project budgeting and contractor/consultant performance results.

A graduate from the University of Nottingham, with a BEng. and MSc. in Mechanical Engineering, prior to joining RAKWA, Abdul was a design consultant engineer for the health care sector, design engineer for alternative energy, and mechanical design engineer for an oil and gas consultancy in Scotland.
